18 of the 31 entities with regulatory epigenomics can be validated against patient tissue; 13 cannot yet

Each row is one entity. The blue point is regulatory epigenomic samples from established cell lines, the orange point the same assays on patient-derived material; the bar between them is the validation gap, annotated as a ratio. MPNST is the widest at 158x.

A row marked none has cell-line data and no patient-derived material of any kind, so a finding made in the model cannot presently be checked against human disease. No entity has the opposite problem.

Restricted to regulatory assays, which is where the asymmetry lives: DNA methylation arrays are mostly run on patient tissue and would mask it.

Thirteen further entities have no regulatory data at all and cannot appear here (Figure WP2D). A fourteenth, LGFMS / SEF, is also absent for a different reason: its entire regulatory record is normal or reference tissue rather than tumor or model, so it has neither point to plot.
