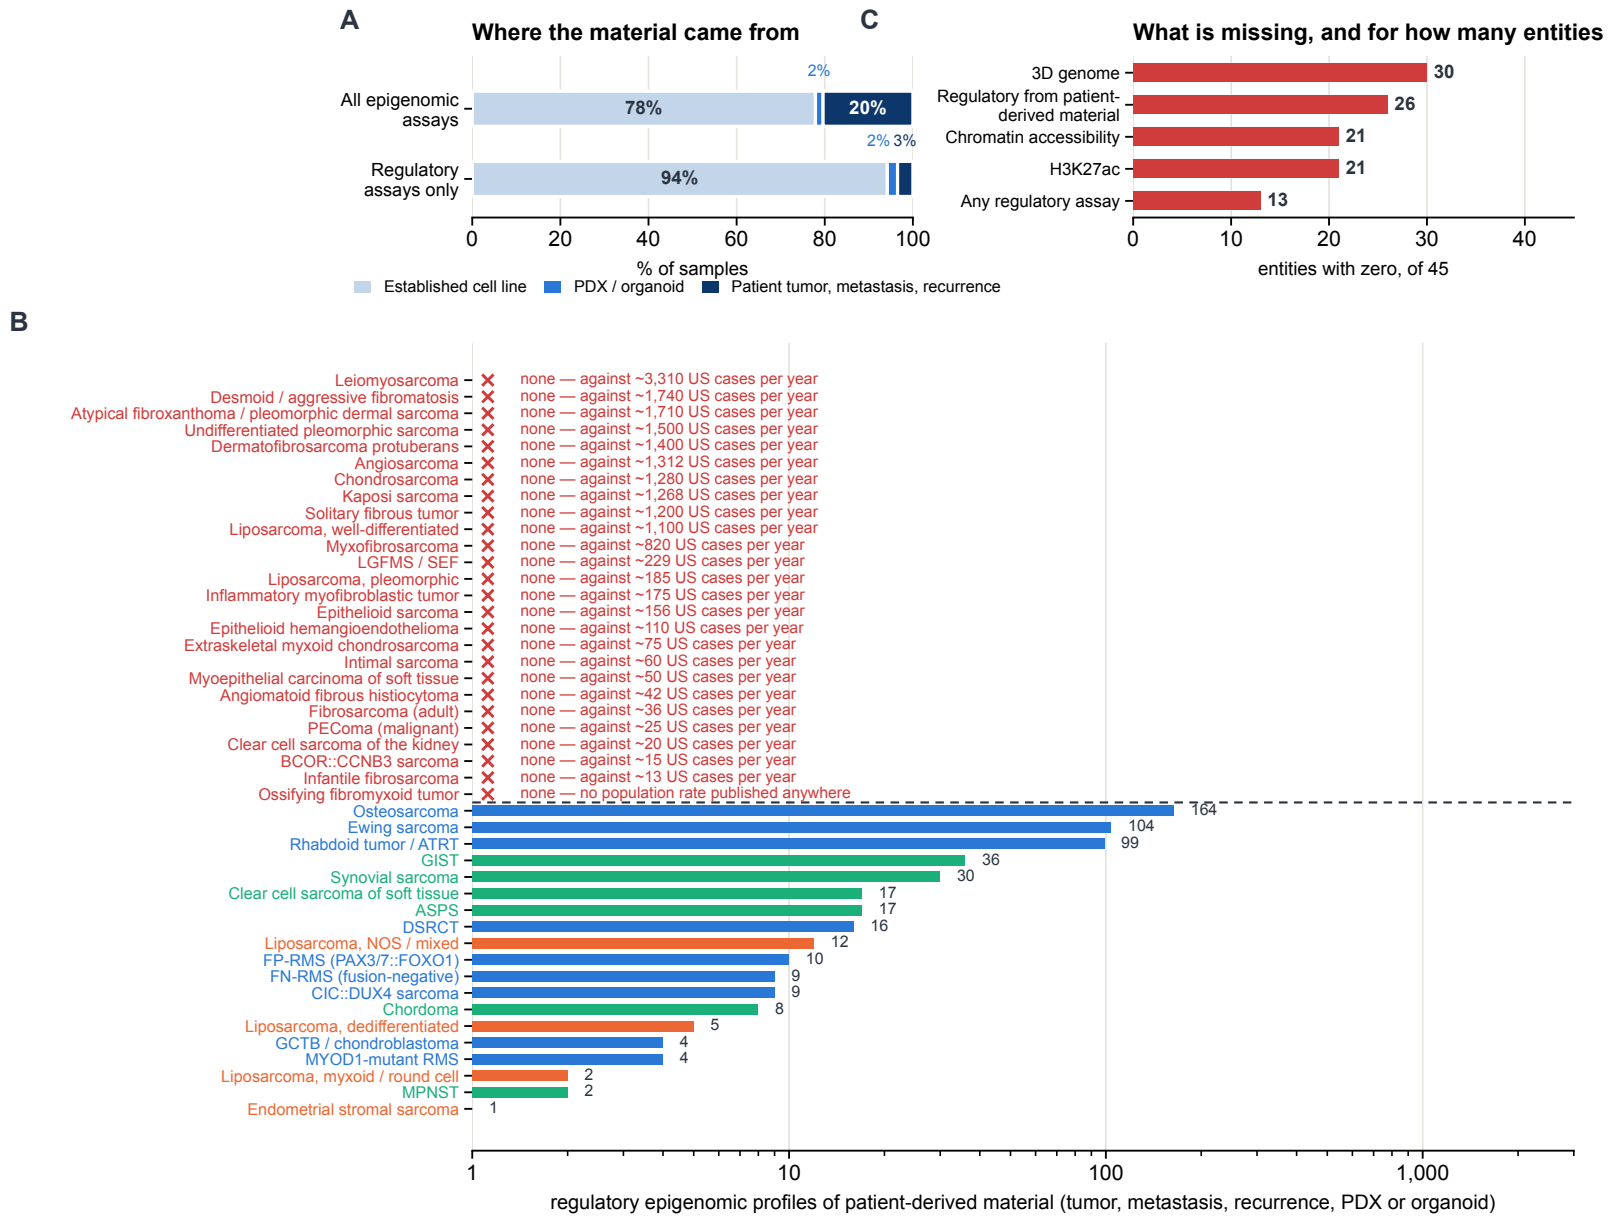
Patient-derived profiling has extended from none to 19 entities in a decade; 26 of 45 remain



Panel A denominator is the 9,485 de-duplicated sarcoma regulatory samples whose material of origin is stated: 94% are established cell lines and 3% are patient tumor. Samples recorded only as normal/reference, mouse or other non-human material, or unspecified are excluded from that denominator rather than assigned by guesswork; against the full de-duplicated set the cell-line share is 87%.

Panel C counts patient-derived material only, which is its purpose; the cell-line side of the same comparison, entity by entity, is Figure WP4. Patient-derived material is kept separate from cell lines because a synovial sarcoma organoid grown from a patient is not a decades-old line, and collapsing the two would report several entities as hard zeros that are not.

Absence indicates no public, entity-labeled deposit rather than evidence that no experiment was performed.
