

Regulatory epigenomics for sarcoma is 92% open. DNA methylation is 39%.

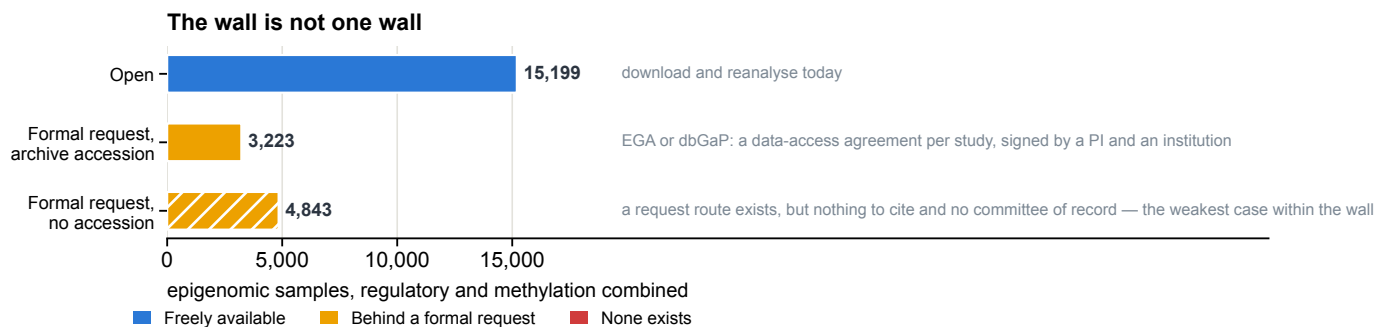

A

B

C

Unit is samples, except CCDI, which resolves to participants — the level at which its metadata resolves. Duplicates removed; ChIP input and IgG controls excluded from the regulatory counts.

The EGA bar includes the St Jude CSTN deposit (469 samples), counted there rather than separately because EGA is where it lives. E-MTAB-9875 (1,974 assays) is held out of the EBI bar: it is the sarcoma methylation classifier, the same material as GSE140686 in GEO. Neither CCDI nor the GDC has ChIP-seq in its assay vocabulary at all, for any disease.

Not one of the 13 entities with no regulatory epigenomics has anything behind the wall either — controlled access explains part of the gap, but none of the hard zeros.
